1. INTRODUCTION

The potential for environmental impacts associated with erosion, sediment transport and salinity has been identified as an issue for further investigation in the Supplemental Environmental Impact Statement (SEIS) for continued development of the Pinedale Anticline Project Area (PAPA). The purpose of this technical report is to describe the conceptual model of the watershed hydrology, summarize the hydrologic transport modeling methods, and to present modeling results that simulate potential impacts resulting from erosion, sedimentation, and salinity.

1.1 Modeling Objectives

The goals of the sediment transport and salinity modeling were to simulate potential erosion and sediment loads entering the Green, New Fork, and Big Sandy rivers and leaving the PAPA boundary and to estimate the potential for salinity loading in the Green and the Big Sandy rivers. The modeling was designed to simulate sediment loading under the following seven conditions:

- Assuming No Disturbance in the PAPA Area (baseline conditions)
- Under the Current Conditions (end of 2006)
- Under the No Action Alternative (end of 2011)
- Under the Proposed Action Alternative (end of 2011)
- Under the Proposed Action Alternative (end of 2023)
- Under Alternative C (end of 2011)
- Under Alternative C (end of 2023)

The results of the watershed modeling for erosion were expressed in soil loss of kilograms per hectare per year. The results of the watershed modeling for sediment transport were expressed in kilograms of sediment per year at the PAPA boundary and in percentage increase over a non-disturbance baseline case and over the current conditions.

1.2 Model Selection

Two different models were chosen to simulate long-term and short-term storm-related erosion and sediment transport for two different spatial scales.

Spatial scale is an important criterion in the selection of a model because the storage characteristics vary at different watershed scales, that is, large watersheds have well developed channel networks and a channel phase, and thus, channel storage is dominant. Such watersheds are less sensitive to short duration, high intensity rainfalls. Alternatively, small watersheds are dominated by the land phase and overland flow, thus they have a relatively less conspicuous channel phase and are highly sensitive to high intensity, short duration rainfalls (Burns et al, 2004).

Storm event watershed modeling was performed using the Kinematic Runoff and Erosion Model (KINEROS2), developed by the U.S. Department of Agriculture (USDA, 2005). KINEROS2 is an event-oriented physically based model that describes the processes of interception, infiltration, surface runoff, and erosion from small agricultural and urban watersheds. KINEROS2 utilizes a network of channels and planes to represent a watershed and the kinematic wave method to route water off the watershed. It is a physically-based model designed to simulate runoff and erosion for single storm events in small watersheds less than approximately 100 km² (10,000 hectares or 24,711 acres). Considering this, KINEROS2 was suitable to model the ephemeral drainages within the PAPA, but could not be used to model the large watersheds of the Green River or the New Fork River.

The model program SWAT (Soil and Water Assessment Tool) was used to simulate large patterns of change in erosion on a large scale assessment over a longer period of time for the Green and New Fork rivers watersheds. SWAT is a distributed lumped-parameter model developed by the USDA Agricultural Research Service (ARS) to predict the impact of land management practices on water, sediment, and agricultural chemical yields in large (basin scale) complex watersheds with varying soils and land use and management conditions over long periods of time (> 1 year). SWAT is a continuous-time model, i.e., a long-term yield model, using daily average input values, and is not designed to simulate detailed, single-event flood routing. Major components of the SWAT model include: hydrology, weather generator, sedimentation, soil temperature, and groundwater and lateral flow (Burns et al, 2004).

Both SWAT and KINEROS2 models were implemented using a public domain geographic information system (GIS) interface, the AGWA (Automated Geospatial Watershed Assessment) tool (Burns et al, 2004). This interface operates in ArcView 3.x GIS and performed the automated parameterization for both models for specified watersheds and basins.

Results from both models are presented for the sixth-level sub-watershed within the PAPA. Sixth level sub-watersheds have a 12-digit Hydraulic Unit Code (HUC). A sub-watershed is defined as typically having an area of 10,000 to 40,000 acres.

1.3 Impact Analysis Approach

The following conditions/alternatives were modeled:

- No Disturbance in the PAPA (baseline conditions)
- Current Conditions (end of 2006)
- No Action Alternative (end of 2011)
- Proposed Action Alternative (end of 2011 and 2023)
- Alternative C (end of 2011 and 2023)

Baseline conditions are based on the vegetation / land cover described in the Wyoming Land Cover Gap Analysis (Wyoming Gap Analysis, 1996) and PAPA-specific vegetation data. Current Conditions and Alternatives were modeled by adding disturbances to the 1996 vegetation. The exact locations of the disturbances are not yet determined, but disturbance percentages per quarter section were given. The total amount of disturbance is the same for the Proposed Action Alternative and Alternative C, but the distribution and development time lines differ. Mitigation measures such as engineered retention structures would likely be implemented, but the mitigation effects were not modeled; therefore, the model results are considered conservative.

2 WATERSHEDS AND SOILS

2.1 Watershed Hydrology

Five perennial streams flow partially through the PAPA: Duck Creek, East Fork River, Green River, New Fork River, and Pine Creek. The majority of the PAPA is drained by intermittent and ephemeral drainages. The PAPA is within the Upper Colorado Region and the Upper Green River Basin and is divided into three sub-basins: Upper Green River, New Fork River, and Big Sandy River. Twenty-one sub-watersheds intersect the PAPA. Of these, twelve drain into the New Fork River, which then flows into the Green River. Five sub-watersheds drain either directly into the Green River, or into the Green River via Alkali Creek. Four sub-watersheds drain into the Big Sandy River (Table 1 and Map 1).

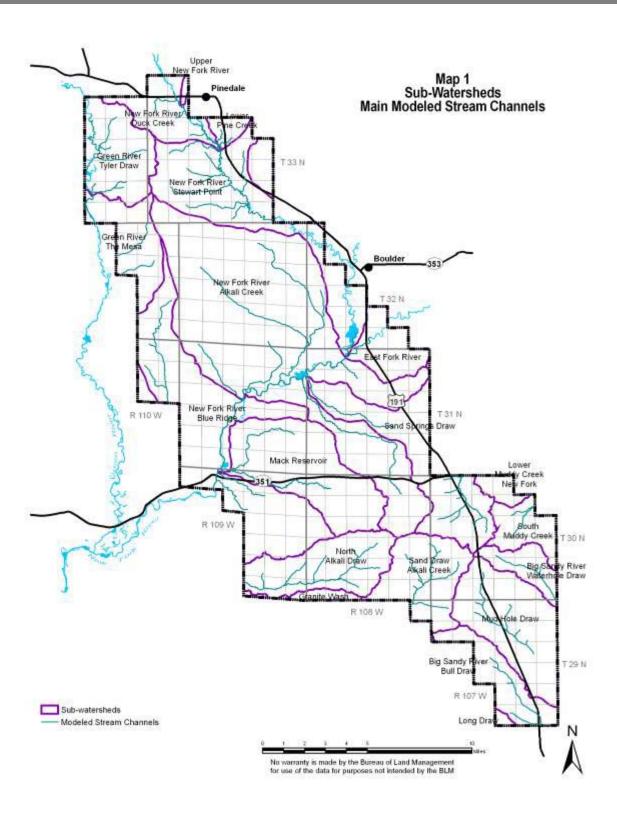

Table 1 Watershed Areas

Sub-Watershed	Sub-Basin	Hydrologic Unit Code (HUC)	Surface Area (acres) in PAPA	Total Surface Area (acres)
Big Sandy River – Bull Draw	Big Sandy River	140401040106	5,761	19,768
Big Sandy River - Long Draw	Big Sandy River	140401040109	316	18,529
Big Sandy River – Waterhole Draw	Big Sandy River	140401040105	3,349	23,876
Mud Hole Draw	Big Sandy River	140401040107	12,923	19,619
East Fork River	New Fork	140401020302	4,885	25,005
Hay Gulch	New Fork	140401020105	245	14,668
Lower Muddy Creek – New Fork	New Fork	140401020603	1,492	34,520
Lower Pine Creek	New Fork	140401020203	1,276	25,749
Lower Pole Creek	New Fork	140401020403	1,757	20,119
Mack Reservoir	New Fork	140401020306	15,353	15,353
New Fork River – Alkali Creek	New Fork	140401020303	49,522	49,532
New Fork River – Blue Ridge	New Fork	140401020305	24,909	39,853
New Fork River – Duck Creek	New Fork	140401020102	5,521	37,229
New Fork River – Stewart Point	New Fork	140401020301	17,216	32,670
Sand Springs Draw	New Fork	140401020304	13,207	19,073
South Muddy Creek	New Fork	140401020602	4,121	33,923
Granite Wash	Upper Green River	140401010704	1,091	12,218
Green River – The Mesa	Upper Green River	140401010404	7,293	41,713
Green River –Tyler Draw	Upper Green River	140401010403	8,834	34,761
North Alkali Draw	Upper Green River	140401010705	9,959	15,918
Sand Draw – Alkali Creek	Upper Green River	140401010701	9,004	22,941

2.2 Erosion, Sediment Transport, and Salt Loading

Soils within the PAPA vary in physical and chemical characteristics as determined primarily by geologic, topographic, and climatic factors. Soils on steeper slopes are especially subject to water erosion and are difficult to reclaim (BLM, 1983). Project activities may increase the potential erosion of these soils, due to the proposed surface disturbance. After major storm events, disturbed soils could be eroded and transported into live streams, if unchecked by appropriate erosion control measures (e.g., reclamation, retention structures).

Increased erosion and sediment transport could lead to increased salinity in the Green River and significant precipitation events could move the dissolved salt to these receiving waters. Salt loading is an issue of concern in the Colorado/Green River system; therefore, any salt loading associated with this project could have implications concerning the Colorado River Basin Salinity Control Act (USBR, 1974).

3 MODEL SETUP

3.1 SWAT and KINEROS2

The watershed modeling was performed using the physically based models SWAT and KINEROS2.

KINEROS2 is an event oriented model, i.e. it is meant to model single storm events. It describes the processes of interception, infiltration, surface runoff, and erosion from small agricultural and urban watersheds during a storm event. Watersheds are represented by a cascade of planes and channels. The partial differential equations describing overland flow, channel flow, erosion, and sediment transport are solved by finite difference techniques. The spatial variations of rainfall, infiltration, runoff, and erosion parameters can be accommodated within the program. KINEROS2 may be used to determine the effects of various artificial features--such as urban developments, small detention reservoirs, or lined channels--on flood hydrographs and sediment yield.

The KINEROS2 model was operated using a public-domain GIS interface, called Automated Geospatial Watershed Assessment or AGWA. AGWA was developed by the USDA, Agricultural Research Service, Southwest Watershed Research Center, in cooperation with the U.S. Environmental Protection Agency (EPA) Office of Research and Development (Burns et al. 2004). AGWA operates in ArcView 3.x GIS and was used to perform the automated parameterization of KINEROS2 for a specified watershed.

SWAT is a continuous time model, i.e. a long-term sediment yield model. The model is not designed to simulate detailed, single-event flood routing. For modeling purposes, a watershed may be partitioned into a number of sub-watersheds or sub-basins. The use of sub-basins in a simulation is particularly beneficial when different areas of the watershed are dominated by land uses or soils dissimilar enough in properties to impact hydrology (Neitsch et al. 2002). SWAT was also operated using AGWA.

3.2 Precipitation and Storm Events

For the two different models, two different types of precipitation data had to be used. SWAT required daily rainfall data for a long period of time, while KINEROS2 required total rainfall depth for a discrete storm event.

Precipitation used for the SWAT input was the daily rainfall data from the gage at Pinedale, Wyoming for the 25- year time period 1980 through 2004. Missing data were filled in with data from the gage at the Boulder Rearing Station (NOAA, 2006). Rainfall was assumed to be uniformly distributed over the entire PAPA. Model runs for SWAT were conducted for the complete 25 year period; the results are then averaged by the model to give the average annual erosion data.

Storm runoff events for KINEROS2 were modeled for 24-hour storms having the following recurrence intervals:

- 5-year
- 10-year
- 20-year
- 50-year
- 100-year, and
- 150-year

Precipitation depths for the 2-year through 100-year storm events were obtained from the National Oceanic and Atmospheric Administration (NOAA) Atlas for Western Precipitation Frequency Maps (NOAA 1973). The precipitation depth for the 150-year storm event was extrapolated from the NOAA data using a semilog plot (Figure 1). Precipitation depths for all storm events are summarized in Table 2.

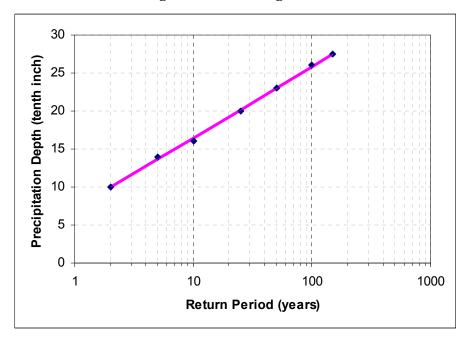

Figure 1. Storm Magnitude

Table 2 Recurrence Interval and Magnitude of 24-hour Precipitation Event

Recurrence Interval T (Years)	Annual Probability	Storm Magnitude x _T (inches)
2	0.5	1.0
5	0.2	1.4
10	0.1	1.6
20	0.04	2.0
50	0.02	2.3
100	0.01	2.6
150	0.0067	2.7

Using AGWA, the precipitation depth is converted to a hyetograph using the Soil Conservation Service (SCS) methodology (SCS 1973) and a type II storm distribution. The precipitation input files for KINEROS2 give the rainfall depth over time, and a sample is shown in Attachment A.

3.3 Elevation Data and Watershed Delineation

The SWAT and KINEROS2 models both calculate flow and erosion in a watershed by assuming each watershed is a connected series of planes and channels. AGWA calculates the planes and channels

necessary for input from digital elevation data. Elevation data from the National Elevation Dataset were downloaded from the U.S. Geological Survey (USGS) EROS Data Center (USGS 2005).

The following elevation data were used: National Elevation Dataset (NED) 1/3 Arc Second, downloaded in ArcGrid NAD 83 Geographic format (vertical datum is GRS 80. For this dataset, the resolution is 10 m. The elevation data were converted to NAD 1983, UTM Zone 12, in meters.

AGWA was then used to delineate the watersheds covering the PAPA and to divide the watersheds into planes and channels for KINEROS2 and SWAT input. This process is described in the AGWA manual (Burns et al. 2004). First, any sinks in the NED data are filled. Sinks are isolated depressions in the elevation surface that can cause flow routing problems. Next, a flow direction grid is created for the entire topographic surface. Then a flow accumulation grid is created. The user then selects a watershed outlet, and the watershed is delineated according to the elevations in the NED file. Ponds or internal gages can be created, but were not used for this project. Lastly, a size for the contributing source area (CSA) of 2.5% or 350 acres, whichever was larger, of the watershed size was selected for all watersheds. CSA is the area that is required before the flow becomes channelized. Smaller numbers result in a larger number of smaller planes and vice versa, so the CSA is a measure of the geometric complexity at which the watershed is delineated. The sub-watershed channels created for input are shown on Map 1.

Discrete channels were created within AGWA, and AGWA-created model channels were generally consistent with the mapped drainage channels. Channel geometry was defined by using the model-default hydraulic geometry relationship options for the channel geometries. These relationships are known as bankfull hydraulic geometry relationships, and they define the bankfull channel width and depth based on watershed size. Bankfull hydraulic geometry relationships are useful in that they define channel topography with minimal input from the user and when actual channel topography is not known or known only for a small portion of actual channels in the watershed (Burns et al. 2004).

3.4 Soils

Properties of the soils in the watersheds can provide estimated input parameters, such as infiltration, water flow, and sediment routing for KINEROS2 and SWAT. The following parameters are estimated for each channel and plane element of each watershed from the soil properties:

Both Models:

• Ks - saturated hydraulic conductivity, in mm/hr

KINEROS2 Parameters:

- CV Coefficient of variation of Ks
- G mean capillary drive, in mm (a zero value sets the infiltration rate to a constant value of Ks)
- Distribution pore size distribution index (or Brooks and Corey Lambda) (This is a parameter used for redistribution of soil moisture during intervals of no flow.)
- Porosity
- Rock volumetric rock fraction, if any
- Splash rain splash coefficient (for plane elements only) (0-1)
- Cohesion cohesion coefficient of bed material, and
- Fractions list of particle class fractions that must sum to one. Fract_sand: fractional sand content (0-1); Fract_silt: fractional silt content (0-1); Fract_clay: fractional clay content (0-1).

SWAT Parameters:

- HydValue weighted hydrologic group value used to determine the runoff curve number.
- CN area-weighted runoff curve number based on soil type and land cover

For KINEROS2, the soil parameters are area-weighted by sub-watershed. For SWAT, these values are based on the dominant soil type found in the sub-watershed.

AGWA estimates these parameters from the State Soil Geographic (Statsgo) database (Burns et al., 2004). However, more detailed soil data are available for the PAPA from the Burma Road Soil Survey (ERO Resources Corporation, 1988) and an on-going survey (Vasquez, 2006). Detailed soil data from both reports were used within the PAPA. The extent of each soil survey within the PAPA is shown in Map 2. The data was put in a database format equivalent to the Statsgo data format. Statsgo soils data were added to the new database for areas where other information was not available. The Statsgo data for Wyoming were downloaded from the NRCS website (NRCS 2005). The database tables created from the Burma Road Soil Survey and the new NRCS survey for the PAPA and surrounding Statsgo soils are shown in Attachment B. The newly created database tables were then used within AGWA to estimate the parameters listed above. The range and average of the parameters estimated from the soils data are shown in Table 3 for KINEROS2 and in Table 4 for SWAT.

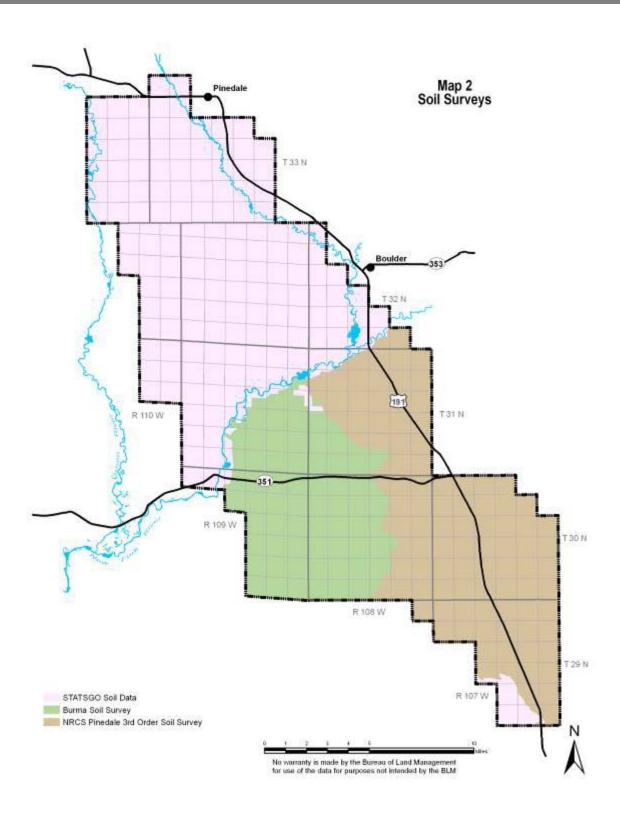

Table 3 KINEROS2 Input Parameters Derived from Soil Properties

	Channel (Constant- AGWA default values)	Plane Average	Plane Minimum	Plane Maximum
Ks (mm/hr)	210	14.84	3.26	36.79
CV	0	1.06	0.53	1.54
G (mm)	101	182.52	88.77	280.98
Distribution	0.545	0.29	0.22	0.32
Porosity	0.44	0.428	0.331	0.465
Rock	0	0.15	0.05	0.48
Splash		106.65	73.30	134.40
Cohesion	0.005	0.006	0.004	0.008
Sand Fraction	0.9	0.51	0.37	0.69
Silt Fraction	0.05	0.27	0.15	0.40
Clay Fraction	0.05	0.22	0.12	0.34

Table 4 SWAT Input Parameters Derived from Soil Properties

	Average	Minimum	Maximum
Ks (mm/hr)	23.90	12.01	41.58
HydValue	1.32	0.98	2.26

3.5 Land Cover

Land cover and vegetation can be used to estimate infiltration parameters and the Manning roughness for KINEROS2 and SWAT. The following parameters have to be estimated for each plane element of each watershed for KINEROS2:

Both Models:

• Manning - Manning roughness coefficient (for plane and channel elements)

KINEROS2 Parameters:

- Canopy fraction of surface covered by intercepting cover (rainfall intensity is reduced by this fraction until the specified interception depth has accumulated)
- Interception interception depth in mm or inches, and

SWAT Parameters:

- CN: area-weighted runoff curve number based on soil type and land cover
- Cover: fraction of surface covered by intercepting cover rainfall intensity is reduced by this fraction until the specified interception depth has been accumulated (0-1)

AGWA can estimate these parameters from the Multi-Resolution Land Characteristics (MRLC) Consortium National Land Cover Data (NLCD).

Two sources were used to obtain the land cover data. For the PAPA, detailed specific vegetation data were developed as grid files. Outside the PAPA, Wyoming GAP land cover data from a map at 1:100,000-scale (http://www.sdvc.uwyo.edu/clearinghouse/metadata/landcov.html) were added to the map. Vegetation types were converted to the closest land cover type defined in the NLCD land cover database. The resulting land cover classification is shown in Map 3. In order to use the AGWA parameter estimation routine, an ID was assigned to each vegetation type according to the NLCD land cover class. Thus, the AGWA lookup table could be used to convert land cover information to modeling parameters. The AGWA look-up table for vegetation data is shown in Attachment C.

The ranges and average of the parameters estimated from land cover data for KINEROS2 are shown in Table 5, and for SWAT in Table 6.

Table 5 KINEROS2 Input Parameters Derived from Land Cover Properties

	Channel (Constant)	Plane Average	Plane Minimum	Plane Maximum
Canopy (no disturbance case)		0.31	0.10	0.70
Interception (no disturbance case)		2.54	0.72	3.00
Manning (no disturbance case)	0.035	0.053	0.025	0.104
Canopy (disturbance cases)		0.25	0.07	0.70
Interception (disturbance cases)		1.98	0.23	3.00
Manning (disturbance cases)	0.035	0.044	0.004	0.158

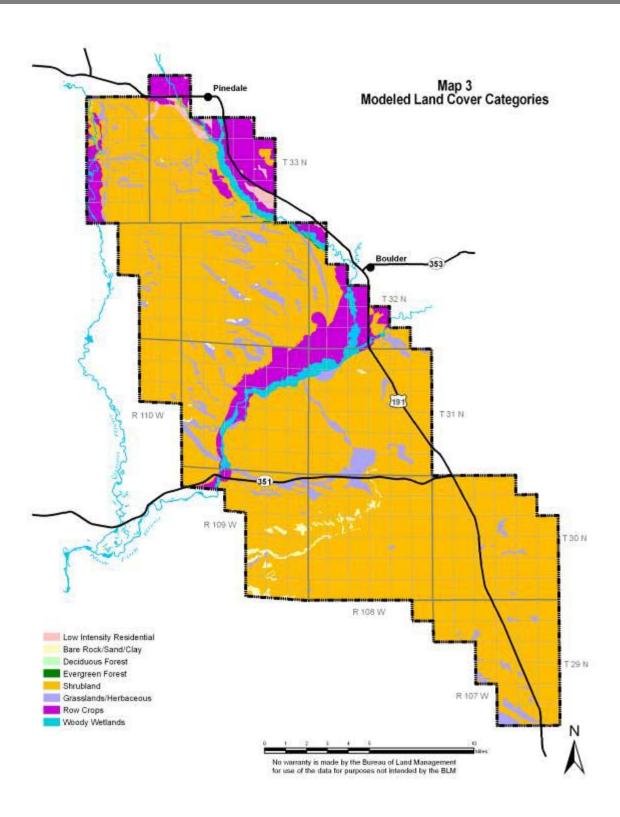

Table 6 SWAT Input Parameters Derived from Land Cover Properties

	Channel (Constant)	Plane Average	Plane Minimum	Plane Maximum
CN (no disturbance case)		86.43	81.12	91.23
Cover (no disturbance case)		28.78	20.60	63.80
Manning (no disturbance case)	0.030	0.050	0.050	0.050
CN (disturbance cases)		87.77	81.12	94.00
Cover (disturbance cases)		25.32	6.93	61.00
Manning (disturbance cases)	0.030	0.050	0.050	0.050

3.6 Disturbance

Disturbances from PAPA developments were simulated for modeling purposes by assuming the land cover changes to equal bare ground, a conservative assumption. Disturbance percentages were given by quarter section for each of the modeled alternatives. The disturbance percentages for each modeled scenario are given in Attachment D. Land cover parameters for each quarter section were changed to simulate the appropriate percentage of disturbance.

3.7 Salt Loading

In the Burma Road Soil Survey (ERO Resources Corporation 1988), chemical analyses of seven soil profiles were performed. The chemical properties of the top layer of saturated soil are summarized in Table 7. The median measured electric conductivity for the 1988 analyzed profiles using the saturated paste method is 0.4 dS/m.

Soil Name	Depth (inches)	Electric Conductivity (dS/m)	Ca (meq/l)	Mg (meq/l)	Na (meq/l)	Sodium Adsorption Ratio
Fraddle	0-4	0.3	1.4	0.7	0.3	0.3
Quard Variant	0-4	0.5	1.2	0.7	3.2	3.3
Dines	0-4	0.4	1.0	0.4	3.0	3.5
Fluvent, Saline- Sodic	0-4	2.5	4.3	1.1	22.4	13.6
Vermillion Variant	0-3	0.3	1.4	1.1	0.3	0.3
Baston	0-3	0.5	0.8	0.5	4.7	6.0
Langspring Variant	0-3	0.4	4.4	1.1	0.3	0.2

Table 7 Soil Profile Chemical Analysis (ERO Resources Corporation 1988)

Electric conductivity was measured with the saturation extract method or saturated paste method. In this method, water is added to the soil until the soil is saturated and just reaches the flow point. This condition is referred to as a saturated paste. The saturated paste is allowed to sit for approximately two hours to reach equilibrium. At that time, the water present in the paste is extracted. This extract is referred to as the saturation extract. The electrical conductivity of this extract is then measured. The higher the salt concentration in a specific soil, the higher the conductivity of the saturation extract.

In ERO Resources Corporation (1988), an estimated electric conductivity is given for all soils in the study area for this report (see also BLM 2005). The estimated average electric conductivity for each soil series and the derived electric conductivity for each soil complex or map unit are shown in Attachment E.

The estimated electric conductivities are given as a range or maximum. The estimated electric conductivity for all watersheds within the PAPA and covered by the Burma Soil Survey is less than 2 dS/m.

The NRCS Pinedale Third Order Soil Survey (Vazquez, 2006) also provides estimates for electric conductivity for all soil types. With the exception of the Havermom-Tismid-Giarch complex, all soils are considered non-saline, with an electric conductivity less than 2 dS/m. In the Havermom-Tismid-Giarch complex salinity ranges from 8-32 dS/m for the top nine inches of Havermon, from 0 to 16 dS/m for the top nine inches of Tismid, and 2-25 dS/m for the top nine inches of eroded Girarch. This complex is found in a narrow band along Sand Spring Draw.

Electric conductivity, which is closely related to total dissolved solids (TDS), can be used as a general measure of salinity. A commonly used conversion states that the TDS in mg/L is roughly equal to 0.67 times the electric conductivity in μ S/cm (Hem, 1989); thus, the average salinity as expressed in TDS for soil water extract is about 268 mg/L for the measured profile average and a maximum of 1,340 mg/L for the estimated salinity range.

4 MODEL RESULTS

Two separate models were used to estimate the average annual erosion in the PAPA, and the sediment transport in channels during storm events. SWAT was used to estimate average annual erosion, and KINEROS2 was used to estimate sediment transport to the PAPA boundary and to the New Fork River within the PAPA.

The same seven scenarios described above were modeled: No Disturbance (Baseline Conditions), Current Conditions (end of 2006), the No-Action Alternative through 2011, Proposed Action Alternative through 2011 and 2023, and Alternative C through 2011 and 2023. For all development scenarios it was assumed that no erosion or sediment control measures would be in place, a conservative assumption.

Of the seven scenarios modeled it was found that the Proposed Action Alternative and Alternative C would cause equal amounts of erosion and sediment loss, both in 2011 and 2023. Thus, even though both of these Alternatives were modeled individually, the discussion of the results from those two alternatives was combined in the following sections.

4.1 Average Annual Erosion (Sediment Loss)

Water-caused erosion (sediment loss) in the PAPA was modeled for 15 of the 21 sub-watersheds intersecting the PAPA. The sub-watersheds modeled were Lower Pine Creek, New Fork River – Duck Creek, New Fork River – Stewart Point, New Fork River – Alkali Creek, East Fork River, Sand Springs Draw, Mack Reservoir, New Fork River – Blue Ridge, Green River – Tyler Draw, Green River – The Mesa, North Alkali Draw, Sand Draw – Alkali Creek, Big Sandy River – Waterhole Draw, Mud Hole Draw, and Big Sandy River – Bull Draw. Of the remaining six watersheds, five, Hay Gulch, Lower Pole Creek, Lower Muddy Creek – New Fork, Long Draw, and Granite Wash, had areas inside the PAPA that were too small to model. South Muddy Creek has a slightly larger area inside the PAPA, but does not contain any disturbance under any of the scenarios, and thus was also excluded from modeling.

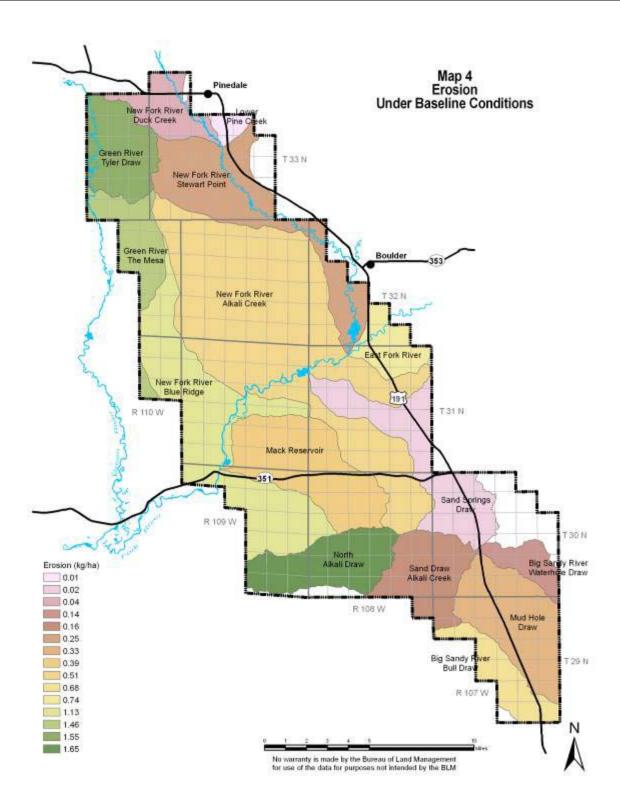

Water-caused erosion is generally low in the PAPA due to low average annual precipitation and low angle slopes. The baseline average sediment loss ranges from less than 0.02 kg/hectare on low angle slopes to approximately 1.5 kg/hectare per year on steeper slopes in the PAPA. A summary of the modeled average annual sediment loss for the 15 sub-watersheds in the PAPA area for baseline conditions and the modeled alternatives is presented in Table 8 and Maps 4, and 5A, 6A, 7A, and 8A. The percent increase in sediment loss compared to baseline conditions is given in Table 9 and Maps 5B, 6B, 7B, and 8B. The percent increase in sediment loss compared to current conditions is given in Table 10

Overall, the projected average increase in sediment loss is 20% for the PAPA, from 0.66 kg/hectare per year for Current Conditions to 0.79 kg/hectare for the Proposed Action Alternative and Alternative C disturbance in 2023. The largest increases in erosion are projected for Mack Reservoir and the New Fork River – Alkali Creek sub-watersheds. Both sub-watersheds contain a large part of the Anticline Crest inside the PAPA. The projected erosion is largest for the largest disturbance, which is projected for the Proposed Action Alternatives and Alternative C in 2023. Of the modeled sub-watersheds, for eight there is no predicted increase or an increase of only 1% in erosion above Current Conditions. These sub-watersheds are the Big-Sandy River – Bull Draw, Big Sandy River – Waterhole Draw, East Fork River, Green River – The Mesa, Green River – Tyler Draw, Lower Pine Creek, New Fork River-Duck Creek, and

Sand Springs Draw. All of these watersheds skirt around the core-development area inside the PAPA, and thus, have less projected disturbances and little projected erosion. In the Mack Reservoir sub-watershed, the total disturbance under the No-Action condition is smaller than the disturbance under the Proposed Action Alternative and Alternative C for 2011; however, the predicted erosion is larger under the No-Action Alternative. This can be explained by noting that the distribution of the disturbed areas is quite different for both alternatives. Under the No Action Alternative, most of the disturbed area is located along the south-east boundary of the sub-watershed. The southeast boundary of the Mack Reservoir sub-watershed has the steepest slopes within the sub-watershed, and is thus much more susceptible to erosion than other less steep areas. The same is true for the sub-watersheds New Fork River - Blue Ridge, and New Fork River - Stewart Point. Sand Draw - Alkali Creek actually has more disturbances under No Action Alternative than under Proposed Action Alternative and Alternative C. Under the Proposed Action Alternative and Alternative C, disturbances are more distributed throughout the watershed, and impact less acreage along the southeast boundary of the watershed. Thus, the impact of erosion is less under the Proposed Action Alternative and Alt

4.2 Sediment Transport during Storms

Based on the results of the erosion modeling, seven sub-watersheds were selected for additional erosion and sediment transport modeling. These watersheds are the New Fork River – Stewart Point, New Fork River – Alkali Creek, Mack Reservoir, New Fork River – Blue Ridge, North Alkali Draw, Sand Draw – Alkali Creek, and Mud Hole Draw.

Of the seven sub-watersheds selected for additional modeling, four are ephemeral sub-watersheds inside the PAPA: Mack Reservoir, Mud Hole Draw, North Alkali Creek, and Sand Draw - Alkali Creek sub-watersheds.

Due to the general low angle slopes in the PAPA, runoff from ephemeral drainages inside the PAPA occurs primarily during large storm events. Most ephemeral drainages do not flow during 5 and 10 year storm events, and thus sediment transport to the New Fork River or the PAPA boundary does not increase during small storms. Erosion and sediment transport may occur on a small scale, but sediment does not travel longer distances to the watershed boundary. Large increases in sediment transport occur only during 25-year or larger storms events. During larger storms, vegetation disturbance (conversion to bare ground) increases the sediment transport significantly. When compared to the No Disturbance (baseline case), sediment transport increases the most for the Proposed Action Alternative and Alternative C in 2023 and the least for the Current Conditions (end of 2006).

The Mack Reservoir sub-watershed drains directly into the New Fork River inside the PAPA. Modeling indicated that flow from Mack Reservoir drainages would not reach the New Fork River until at least a 50-year storm event takes place. Sediment transport would be largest under a 150 year storm (Table 11), but relative increase over baseline or current condition would be largest under a 50 year storm. Sediment transport would increase approximately 4 times over baseline conditions (Table 12), and 1.5 times over current conditions under a 50-year storm (Table 13).

Mud Hole Draw drains into Big Sandy River, and North Alkali Draw and Sand Draw drain into the Green River via Alkali Creek. Sediment transport to the PAPA boundary was modeled for all three subwatersheds. For all three sub-watersheds, sediment transport would be largest under a 150 year storm (Table 14, Table 17, and Table 20). For Mud Hole Draw, relative sediment transport increase over baseline or current condition would be largest under a 50 year storm. Sediment transport would increase approximately 70% over baseline conditions (Table 15), and 30% over current conditions (Table 16). For North Alkali Draw, relative sediment transport increase over baseline or current condition would be largest under a 150 year storm. Sediment transport would increase approximately 20% over baseline conditions (Table 18), and 10% over current conditions (Table 19).). For Sand Draw, relative sediment transport

increase over baseline or current condition would be largest under a 25 year storm. Sediment transport would increase approximately 20 times over baseline conditions (Table 21), and 4 times over current conditions (Table 22).

Sediment is transported to and within the New Fork River. Three large sub-watersheds of the New Fork River are within the PAPA, New Fork River - Stewart Point, New Fork River - Alkali Creek, and New Fork River - Blue Ridge. Under the Proposed Action Alternative and Alternative C, all three sub-watersheds would experience increased sediment transport in the New Fork River, caused by flow from ephemeral drainages into the New Fork River as well as from direct sediment washing into the stream. Each sub-watershed of the New Fork River is larger than can be modeled with KINEROS2. KINEROS2 is designed to simulate runoff and erosion for single storm events in small watersheds less than approximately 100 km² (~25,000 acres). Stewart Point sub-watershed contains over 32,000 acres, Blue Ridge contains almost 40,000 acres, and Alkali Creek contains almost 50,000 acres. In addition, the three sub-watersheds cannot be considered independently of each other, and should be modeled together, because changes in the upstream flow regime of the New Fork River will influence the downstream flow in the lower sub-watersheds. Increases in sediment load were estimated for the New Fork River; however, it has to be noted that these are very rough estimates, calculated by assuming the different sections of the New Fork River can be considered independently. Estimates for sediment yield increases for the New Fork River are given in below (Table 22, Table 23, Table 24, Table 25, Table 26, Table 27, and Table 28.)

All modeling is based on assumptions and many simplifications are inherent when creating input parameters for SWAT and KINEROS2. Thus, the actual values of sediment transported should be considered with caution. However, the differences in model-derived sediment transport volumes among the analyzed conditions/alternatives and among precipitation events provide approximate values suitable for comparison. Specific monitoring and sampling in the PAPA channels would provide more accurate data of environmental conditions, and if conducted, these data could be compared with the model results presented herein for verification.

4.3 Salt Loading to Green River

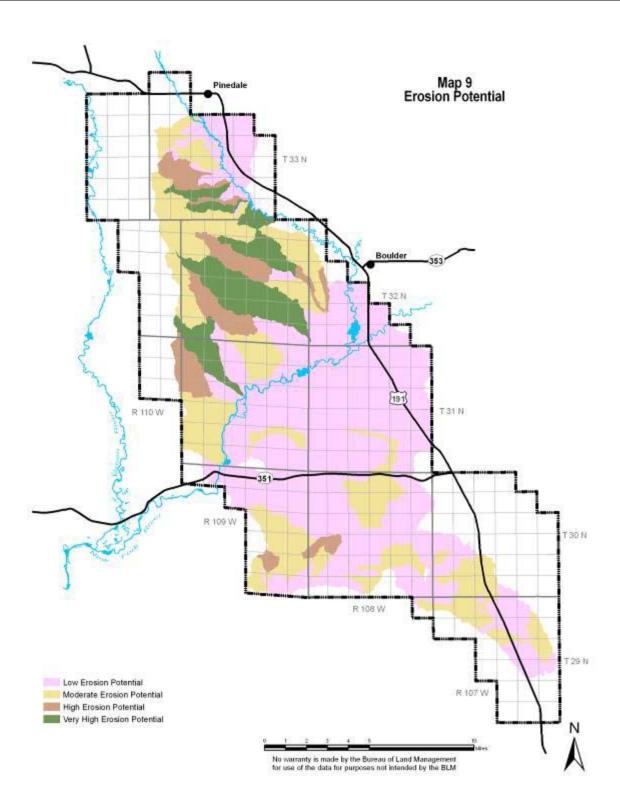

Salinity in all waters leaving the PAPA was estimated as ranging from approximately 300 to 1,300 mg/L as total dissolved solids (TDS). Salinity at the PAPA boundary can be estimated from the measured soil saturation extract salinity or electric conductivity. The saturation extract salinity is assumed to be the maximum salinity of water in contact with sediment. Actual salinity may be lower, if the contact time between water and sediment is not long enough to reach equilibrium or if only a portion of the water volume is in contact with the sediment; both of these conditions are likely during most storm events. Saturation extract salinity has been measured for only seven of the various soil series within the PAPA and was estimated for the other soil series, so only a rough estimate for the maximum salinity for all subwatersheds can be provided.

Measured salinity in the New Fork River near Big Piney (USGS, 2006) ranges from 40 mg/L TDS (0.06 dS/m) to 280 mg/L TDS (0.42 dS/m), with an average of 130 mg/l TDS (0.19 dS/m), based on 283 USGS measurements of specific conductance between 1965 and 1986. Storm runoff from the PAPA is likely higher in salinity, and even under undisturbed conditions would add additional salt loading to the New Fork, and thus the Green River. Increased sediment load from increased disturbances would increase the salinity added to the New Fork and the Green River. Field measurements of salinity in flowing streams could quantify the salt loading under current conditions.

4.4 Areas Most Susceptible to Erosion

Erosion potential depends on slope, soil type, and vegetation cover. Since most of the development within the PAPA will take place on the Anticline Crest, erosion potential for the Anticline Crest was analyzed for this study. To delineate areas within the Anticline Crest with the greatest potential for erosion, subwatersheds were subdivided into smaller sections and were analyzed for their sediment yield under the No Disturbance (baseline conditions) scenario for a 150-year storm. However, the ranking of the subwatersheds across alternatives with respect to erosion potential would not change under any other rainfall scenario.

Areas (sub-watersheds) along the steeper ridges within the PAPA have the greatest potential for erosion after disturbance. Map 9 illustrates the potential for erosion in the PAPA. The erosion potential is given as "low", "moderate" "high", and "very high". This is a relative classification scheme based on the overall erosion potential inside the PAPA. Areas with "low" erosion potential have erosion potential less than the mean erosion potential inside the PAPA, "moderate" erosion potential signifies the mean erosion potential inside PAPA (erosion potential ranges from mean to mean plus one standard deviation), "high" signifies the erosion potential ranges from mean plus one standard deviation to mean plus two standard deviations, and "very high" signifies erosion potential is higher than mean PAPA erosion potential plus two standard deviations.

5 CONCLUSIONS

All model alternatives increase erosion and sediment transport into and from the PAPA. Modeled erosion and sediment transport is largest for the Proposed Action Alternative and Alternative C in 2023. Erosion and sediment transport also increase with rainfall intensity. The New Fork River flows directly through the PAPA and additional sediment from erosion would flow into the New Fork River and, thus, also reach the Green River. The modeling assumed that no measures were taken to prevent erosion and sediment transport. However, due to the proximity of the New Fork River and Green River, best management practices (e.g., revegetation, sediment control structures) would have to be used to prevent erosion and minimize sediment transport. Areas and sub-watersheds that are most susceptible to erosion, and create the largest amount of sediment have been identified, and these areas are recommended to receive the most aggressive monitoring (e.g., photo-point, vegetation, channel cross section, first flush) and soil erosion control measures/treatments.

Impact Summary for Proposed Action Alternative and Alternative C:

- Average annual water-caused erosion in the PAPA area would increase above current conditions. The increase would be 11% for disturbances expected in the year 2011 and 20% for disturbances in the year 2023. This assumes no erosion control measures, mitigation or reclamation takes place.
- Sediment transport from ephemeral drainages into the New Fork River would increase significantly during 25-year and larger storm events. From the Mack Reservoir sub-watershed, sediment transport into the New Fork River would increase approximately 1.5 times during a 50-year storm over a 50-year storm occurring under current conditions.
- Sediment transport from ephemeral drainages to the PAPA boundary would increase significantly during 25-year and larger storm events. Most affected would be the Sand Draw sub-watershed. Sediment transport to the PAPA boundary would increase approximately 4 times during a 25-year storm over a 25-year storm occurring under current conditions.
- Salinity in runoff from disturbed areas would increase and could potentially increase salt loading in the Green River.
- All statements above assume no erosion control measures, mitigation or reclamation takes place.

ATTACHMENT B: SOIL DATABASE TABLES

Soil data from the Burma Soil Survey (ERO 1988) and the new NRCS survey for the PAPA were put into Statsgo format, in order to allow AGWA to read the data and use it to estimate the infiltration, runoff, and sediment transport parameters. The first soil database table from the Statsgo data which AGWA reads is called comp.dbf. This file contains the following fields:

STSSAID State Soil Survey Area ID
MUID Map Unit Identification
SEQNUM Sequence Number
MUSYM Map Unit Symbol
COMPNAME Component Name

S5ID Soil Interpretations Record Number

COMPPCT Component Percent
SLOPEL Soil Slope (Minimum)
SLOPEH Soil Slope (Maximum)
SURFTEX Surface Soil Texture

OTHERPH Phase Class (other than slope or texture)

COMPKIND Kind of Component (S=Series, F=Family, V=Variant, M=Miscellaneous)

COMPACRE Component Acres

CLASCODE Taxonomic Classification Code

ANFLOOD Annual Flooding Frequency (Descriptive)

ANFLODUR Flood Duration Class (Descriptive)

ANFLOBEG Month in which annual flooding begins in a normal year ANFLOEND Month in which annual flooding ends in a normal year

GSFLOOD Growing Season Flooding (Descriptive)

GSFLODUR Growing Season Flood Duration (Descriptive)

GSFLOBEG Month in which annual flooding begins during growing season GSFLOEND Month in which annual flooding ends during growing season

WTDEPL Depth to high Water Table (Minimum)
WTDEPH Depth to high Water Table (Maximum)

WTKIND Water Table Kind (Artesian, Perched, Apparent)

WTBEG Month in which seasonal water table occurs at the depth specified in a normal year

WTEND Month in which seasonal water table subsides below the normal year depth

PNDDEPL Ponding Depth (Minimum)
PNDDEPH Ponding Depth (Maximum)

PNDDUR Ponding Duration

PNDBEG

PNDEND

ROCKDEPL Depth to Bedrock (Minimum) Inches ROCKDEPH Depth to Bedrock (Maximum) Inches ROCKHARD Bedrock Hardness (Descriptive)

PANDEPL Depth to Cemented Pan (Minimum) Inches PANDEPH Depth to Cemented Pan (Maximum) Inches PANHARD Cemented Pan Thickness (Descriptive)

SUBINITL Min. value in initial subsidence when drained, in inches (organic soils only)
SUBINITH Max. value in initial subsidence when drained, in inches (organic soils only)

SUBTOTL Min. value in total subsidence when drained, in inches (organic soils only)
SUBTOTH Max. value in total subsidence when drained, in inches (organic soils only)

HYDGRP Hydrologic Group

FROSTACT Potential Frost Action (Descriptive)

DRAINAGE Code identifying the natural soil drainage condition. Example: Well Drained (W);

Excessive (E); Moderately Well (MW); Poorly (P); Somewhat Excessively (SE);

Somewhat Poorly (SP)

HYDRIC Hydric Soil Rating

CORCON A rating of concrete susceptibility to corrosion when in contact with the soil
CORSTEEL A rating of the uncoated steel susceptibility to corrosion when in contact with soil

CLNIRR A rating of the soil for nonirrigated agricultural use

CLIRR Irrigated Capability Class
SCLNIRR Irrigated Capability Subclass
SCLIRR Irrigated Capability Subclass
PRIMFML Prime Farmland Classification

From this table, AGWA reads the composition percentages and surface texture for each soil. Table B-1 presents the part of the comp.dbf table read by AGWA and populated with data from the Burma Soil Survey and the new NRCS survey for the PAPA. MUID numbers between PD100 and PD129 indicate soil data from the Burma Survey, MUID numbers higher than PD400 indicate soil data from the NRCS survey.

Table B-1: Composition percentages and Textures for PAPA Soils

The second soil database table from the Statsgo data, which AGWA reads in order to estimate the infiltration, runoff, and sediment transport parameters, is called layer.dbf. This file contains the following fields:

STSSAID State Soil Survey Area ID
MUID Map Unit Identification
SEQNUM Sequence Number

S5ID Soil Interpretations Record Number

LAYERNUM Layer Number

LAYERID convention to identify the original layers on the Number SOI-5 record. Example:

layerid 11 for the first surface of a multisurface record, 12 for the second surface

layer, 2 through 9 for subsurface layers

LAYDEPL depth to upper boundary of soil layer, inches depth to lower boundary of soil layer, inches

TEXTURE1 TEXTURE2 TEXTURE3

KFACT Soil Erodibility Factor, includes adjustment for rock fragments

KFFACT Soil Erodibility Factor, without adjustment for rock fragments Used in SWAT

TFACT Soil loss tolerance factor. WEG Wind Erodibility Group

INCH10L weight of the rock fragments greater than 10 inches size, in percent (minimum) weight of the rock fragments greater than 10 inches size, in percent (maximum)

INCH3L weight of the rock fragments 3 to 10 inches size, in percent (minimum) Weight of the rock fragments 3 to 10 inches size, in percent (maximum)

Percent Passing Sieve Number 4 (Minimum) NO4L NO4H Percent Passing Sieve Number 4 (Maximum) Percent Passing Sieve Number 10 (Minimum) NO10L NO₁₀H Percent Passing Sieve Number 10 (Maximum) NO40L Percent Passing Sieve Number 40 (Minimum) Percent Passing Sieve Number 40 (Maximum) NO40H Percent Passing Sieve Number 200 (Minimum) NO200L **NO200H** Percent Passing Sieve Number 200 (Maximum)

CLAYL
Clay Content of Material less than 2 mm in size (Minimum)
CLAYH
Clay Content of Material less than 2 mm in size (Maximum)
LLL
Liquid Limit in percent moisture by weight (Minimum)
LLH
Liquid Limit in percent moisture by weight (Minimum)

PIL Plasticity Index (Minimum)
PIH Plasticity Index (Maximum)

UNIFIED1 Unified Soil Classification (engineering)
 UNIFIED2 Unified Soil Classification (engineering)
 UNIFIED3 Unified Soil Classification (engineering)
 UNIFIED4 Unified Soil Classification (engineering)

Soil properties to a depth of 9 inches are averaged.

The percent passing designated sieves in this table is used to calculate the KINEROS parameter for the rock fraction in the soil.

From the averaged layers and percentage composition of soils for each map unit, a texture is determined. From this texture, the other KINEROS parameters are estimated in AGWA, according to the kin-lut.dbf table (Table B-3).

Table B-3: AGWA Conversion from Soil Texture to KINEROS Input

Total Modeled Disturbance	5059.4	8824.2	10151.3	10155.3	15030.9	15024.4

Total modeled disturbance is not exactly equal to total estimated potential disturbance, since estimates changed from the time modeling was conducted. However, modeling is considered conservative, and small increases in estimated potential disturbance would not change modeling results.
